

- The chart shows the level of CO₂ and the average temperature on our planet lasts 800.000 years .
- The global average temperature and the amount of CO₂ can be determined from the air bubbles in the ice of the antartica.
- 25 000 years before now, big parts of our continents were covered in ice. The global average temperature was about 6°C lower than today.
- To reach 300ppm, about 960 billion tons of CO₂ must be removed out of the air.
- 1ppm ~ 7,8 billion tons CO₂.

Increase of CO₂ in the atmosphere

- Each year humans emit about 40 billion tons of CO₂.
- 20 billion tons (~3ppm) are absorbed by plants (photosynthesis).
- The rest of CO₂ remains in the air.
